## Description

The invention relates to a seamless soft capsule containing encapsulated filling substances, at least one encapsulating wall being formed of a material different from a material forming another encapsulating wall.

Furthermore, the invention relates to a method for producing said soft capsule, which comprises:

- (a) preparing a composite jet stream consisting of a stream of a film-forming liquid substance for forming an encapsulating wall and within said stream of a film-forming substance a single stream, or a plurality of independent streams, of a filling substance having flowability,
- (b) advancing the composite jet stream into and through a stream of a liquid medium substantially incapable of dissolving the film-forming liquid substance in the flowing direction of the liquid medium stream,
- (c) obtaining soft capsules from a predetermined length of the composite jet stream successively from its leading end in the liquid medium stream, and
- (d) solidifying the walls of the resulting soft capsules.

A multicellular soft capsule having its inside partitioned by a film was recently proposed in JP-A-60/109 520 (see PATENT ABSTRACTS OF JAPAN, Vol. 9, No. 254 (308), 1977, October 11, 1985). This document states that the multicellular soft capsule is obtained by partitioning a soft capsule shell composed of an upper film and a lower film into two cells by means of a partitioning film, and filling different drugs into the two cells. As a result, two drugs which are not desired to be mixed can be stably included in a single soft capsule. By using materials having different solubilities and dissolving speeds, it is possible to cause one part of a single capsule to be released and absorbed in the stomach and the other part, in the intestines. It is also possible to make one part of the capsule fast-releasing and the other part slow-releasing.

Since the proposed multicellular soft capsule is produced by a rotary method or a flat plate method, the capsule shell has seams. Hence, in spite of the aforesaid advantages, it has the defect that the filled drugs leak from the seams, or air comes through the seams to deteriorate the contents oxidatively. Furthermore, by the rotary method or the flat plate method, it is difficult to produce multicellular soft capsules having a small size, and moreover, the cost of production becomes high. Furthermore, since both surfaces of the partitioning film in the aforesaid multicellular soft capsule are formed of the same material, if a drug to be filled in one of the cells reacts with the components of the partitioning film, it cannot be included in such a cap-

sule.

Furthermore, a seamless soft capsule and a method for producing said soft capsule of the types mentioned in the beginning are described in EP-A-0 116 311. In detail, this document discloses a multiple soft capsule wherein one or more inner soft capsules are contained together with outer capsule liquor in an outer soft capsule, i.e. the filling of the outer soft capsule consists of the outer capsule liquor and an inner soft capsule "swimming" within said liquor. The inner capsule in turn can have a filling consisting of an inner capsule liquor and a secondary inner capsule "swimming" within said inner capsule liquor, etc. Thus, as regards the cross-sectional structure of this capsule, EP-A-0 116 311 proposes a concentric multi-circular soft capsule.

A soft capsule of such structure as disclosed in EP-A-0 116 311 has some significant disadvantages. One of these disadvantages is, that the release of a liquor contained in an inner capsule is not independent of the release of the outer capsule liquor. If e.g. two different liquid pharmaceutical substances which must be stored separately within the capsule, are to be released at the same time, this will not be possible. Another disadvantage is, that the selection of wall materials is limited because the wall material of an inner capsule "swimming" in the liquor of the outer capsule has to be stable against both the liquor contained within this inner capsule and the outer capsule liquor.

It is an object of this invention to provide a multicellular seamless soft capsule free from the aforesaid defects.

Another object of this invention is to provide a simple and inexpensive method of producing the aforesaid seamless soft capsule, which can easily give capsules of a small size as well.

Further objects and advantages of this invention will become apparent from the following detailed description.

According to one aspect of this invention, there is provided a seamless soft capsule of the type mentioned in the beginning which is characterized in that said soft capsule being composed of a plurality of cells, coalesced to each other, said filling substances being encapsulated in the individual cells, the wall of at least one of said cells being formed of a material different from a material forming the wall of at least one of the other cells.

According to another aspect of this invention, the seamless soft capsule of this invention is produced by a method of the type mentioned in the beginning which is characterized in that

(1) step (a) comprises preparing a plurality of composite jet streams each consisting of a stream of film-forming liquid substance for forming a cell wall and within said stream of a film-

forming liquid substance a single stream, or a plurality of independent streams, of a filling substance having flowability, the film-forming liquid substance in at least one of the composite jet streams being different from the film-forming liquid substance in at least one of the other composite jet streams,

(2) step (b) comprises advancing the plurality of composite jet streams in closely spaced relationship into and through said stream of a liquid medium substantially incapable of dissolving the film-forming liquid substance in the flowing direction of the liquid medium stream,

(3) an additional step is provided between steps (b) and (c), said additional step comprises coalescing the adjacent composite jet streams to each other to form a single composite jet stream in the liquid medium stream,

(4) step (c) comprises cutting said single composite jet stream obtained from said coalescing, to a predetermined length successively from its leading end in the liquid medium stream, and

(5) step (d) comprises solidifying the cell walls of the resulting soft capsule.

The capsule and the method of producing it in accordance with this invention will be specifically described with reference to the accompanying drawings in which:

Figure 1 is a systematic view, partly in section, of one example of an apparatus used to practice the method of this invention in its entirety;

Figure 2 is an enlarged end view of a composite nozzle in the apparatus shown in Figure 1;

Figure 3 is an enlarged sectional view of a seamless soft capsule produced in accordance with this invention by the apparatus of Figure 1;

Figure 10 is an end view of a further example of the composite nozzle;

Figure 11 is a sectional view of a soft capsule produced by using the composite nozzle of Figure 10; and

Figure 12 is an enlarged sectional view of the principal parts of a still further example of the

composite nozzle.

In Figure 1, the reference numeral 1 represents a tank holding a film-forming liquid substance A for forming a cell wall; 2, a tank holding a film-forming substance B which is different from the substance A; 3, a tank holding a filling substance C; and 4, a tank holding another filling substance D. The tanks 1, 2, 3 and 4 are individually provided with heating means (not shown) for maintaining the substances A, B, C and D at suitable temperatures for maintaining them flowable. The substances A, B, C and D are supplied to the tanks 1, 2, 3 and 4 respectively. Metering pumps 11, 21, 31 and 41 are provided for feeding the substances A, B, C and D of the tanks 1, 2, 3 and 4 to a composite nozzle 5. The composite nozzle 5, as shown in Figures 1 and 2, is a duplex nozzle consisting of outside nozzles 51 and 52 having a semielliptical cross sectional shape resulting from partitioning an elliptical tube by a partitioning wall 50 at its center and inside nozzles 5a and 5b of a smaller diameter disposed nearly centrally in the outside nozzles 51 and 52 respectively. The outside nozzles 51 and 52 communicate with the tanks 1 and 2, and the inside nozzles 5a and 5b, with the tanks 3 and 4. The composite nozzle 5 faces downwardly along a downwardly flowing stream of a liquid medium e within a capsule-forming tank 6.

The specification of the composite nozzle 5 may be freely changed according, for example, to the use of the capsule to be produced. For example, for use in making a capsule used as a medicine, a typical specification is that in Figure 2, the elliptical tube has an outside long diameter  $d_L$  of 5 to 20 mm and an outside short diameter  $d_S$  of 3 to 12 mm, and the inside nozzles have an outside diameter of  $d_i$  of 2 to 9 mm, and the individual tubes have a thickness of 0.1 to 2 mm.

The liquid medium e formed, for example, of liquid paraffin is sent to a heat exchanger 72 from a recovery hopper 7 concurrently acting as a storage tank by means of a pump 71. In the heat exchanger 72, it is cooled to a moderate temperature of, for example, about 5°C and supplied to the upper portion of the capsule-forming tank 6. It becomes a downwardly flowing stream within the capsule-forming tank 6, and is circulated to the recovery hopper 7 via a capsule recovery tube 61. A part of the liquid medium e is supplied to a pulse stream-forming device 74 by means of a pump 73 from the hopper 7. It is converted to a regular pulse stream in the pulse stream-forming device 74 and supplied to a pulse stream nozzle 8 provided within the capsule-forming tank 6.

The pulse stream nozzle 8 is a circular nozzle provided immediately below, and coaxially with, the composite nozzle 5 and having a slightly larger diameter than the diameter of the elliptical tube of

the composite nozzle 5. A pulsating stream of the liquid medium e from the nozzle 8 is extruded toward the center of the nozzle 8 from an annular slit formed within the nozzle 8 in such a manner as to surround a single composite jet stream formed by the composite nozzle 5

Film-forming liquid substances A and B for cell wall formation and filling substances C and D to be filled in a capsule are sent under pressure to nozzles 51, 52, 5a and 5b constituting the composite nozzle 5 by means of the metering pumps II, 2I, 3I and 4I. From the nozzle 51, a composite jet stream composed of a stream of the film-forming substance A and a single stream of the filling substance C is extruded into, and along, the downwardly flowing liquid medium flow within the capsule-forming tank 6, and from the nozzle 52, a composite jet stream composed of a stream of the film-forming substance B and a stream of the filling substance D is likewise extruded into, and along, the downwardly flowing liquid medium stream within the capsule-forming tank 6. Since the nozzles 51 and 52 form an integral unit via a partitioning wall 50, the two composite jet streams extruded as above, nearly simultaneously with their formation, are coalesced to each other into a single composite jet stream within the downwardly flowing stream of the liquid medium e owing to the surface tensions of the film-forming liquid substances A and B.

The speeds of extruding the composite jet streams, and the flow rate of the downwardly flowing stream of the liquid medium e can be varied depending upon, for example, the types of the film-forming liquid substances forming the composite jet streams, the type of the liquid medium e and the size of the composite nozzle, and any skilled person in the art would be able to determine optimum conditions easily by routine experiments. As tentative standards, it is convenient to adjust the extruding speed of each composite jet stream to about 4 to 40 m/min., and the flow rate of the downwardly flowing liquid medium stream to about 5 to 50 m/min.

The single composite jet stream so formed undergoes impact of the regular pulse stream of the liquid medium e from the pulse stream nozzle 8, whereby as shown in Figure 1, necks or narrowed parts are formed at certain intervals beginning with its leading end. The jet stream is drawn downwardly by the downwardly flowing stream of the liquid medium e, and successively cut off at the neck portions by the downwardly drawing force. Each cut droplet f contains the filling substances C and D encapsulated in the film-forming liquid substances A and B by the surface tension of the substances A and B, and is formed into a seamless capsule, which is roundish as a whole, while mov-

ing down through the downwardly flowing stream of the liquid medium e. The capsules formed advance to the hopper 7 via the recovery tube 6I while being cooled and solidified. In the hopper 7, the capsules are separated from the liquid medium e by a separator 70, supplied to a conveyor 9 provided on one side of the separator 70, and sent to a drying step where they are dried to produce a final product.

By the method described above, there are obtained unitary seamless soft capsules 10 in which a cell a formed of the film-forming substance A and the filling substance C encapsulated in it is coalesced to a cell b formed of the film-forming substance B which is different from the substance A and the filling substance D encapsulated in it, and the cell wall is of a double structure at the coalesced part, as shown in Figure 3.

The film-forming substance for cell formation may be any material which can be formed into a thin film from its melt or solution, and after film formation can be solidified by cooling and/or drying. Substances usually employed in forming the shell of a soft capsule may be used in this invention. Examples include film-forming substances composed of gelatin or gelatin derivatives such as succinic gelatin and incorporated therein, plasticizers [such as glycerol, sorbitol, propylene glycol and Carbowax (polyethylene glycol)], essences and flavors (such as peppermint oil, cinnamon oil and strawberry), dyes (such as yellow No. 4, yellow No. 5, red No. I, blue No. I and copper chlorophyllin), opacifying agents (such as titanium dioxide and red iron oxide), solubility controlling agents (such as cellulose acetate phthalate, alkali metal salts of hydroxypropylmethyl cellulose, alkali metal salts of hydroxymethyl cellulose acetate succinate, alkali metal salts of alginic acid, alkali metal salts of polyacrylic acid, methyl cellulose, carboxymethyl cellulose, casein, collagen, agar powder, polyvinyl alcohol and pectin)), etc. selected as desired. It is generally used as a liquid by dissolving it in water under heat.

The filling substance to be encapsulated in each cell of the soft capsule of this invention can be any drug which does not dissolve the cell wall nor react with the components of the cell wall. It is preferably liquid when it is to be filled in the cell in accordance with the method of this invention. Accordingly, when the drug is a solid, it is desirably filled in a flowable state as a solution, emulsion or suspension.

According to the method of this invention, by using a combination of two or more suitable film-forming substances selected from those exemplified above, at least one of a plurality of cells constituting the resulting soft capsule can have a different dissolving time in the digestive tract from

at least one of the other cells (for example, whether fast-releasing or slow-releasing), or at least one cell may have different dissolving characteristic from at least one of the other cells (for example, whether released and adsorbed in the stomach or the intestines).

Furthermore, in the present invention, the filling substances to be encapsulated in the cells may be varied from cell to cell. As a result, a single capsule may be obtained in which a drug expected to be fast-acting is filled in a fast-dissolving cell and a drug desired to be slow-acting is filled in a slow-dissolving cell. Alternatively, a single capsule cell may be obtained in which a drug expected to develop its effect in the stomach is filled in a cell soluble at the stomach, and another drug expected to develop its effect in the intestines is filled in a cell soluble at the intestines.

The shape of the soft capsule 10 can be selected by changing the shape of the end surface of the composite nozzle 5 on the extrusion side. Some modified examples of the composite nozzle 5 will be described below.

The composite nozzle 5 shown in Figure 4 is composed of duplex outside nozzles 51 and 52 having a cocoon-shaped cross section and smaller-diameter inside nozzles 5a and 5b disposed coaxially within the outside nozzles 51 and 52 respectively. The capsule 10 obtained by using this composite nozzle 5 has a cocoon-shaped cross-section as shown in Figure 5. It is a seamless soft capsule in which filling substances c and d are independently encapsulated in cells a and b.

Figures 6 and 8 show other examples of the composite nozzle 5. These nozzles 5 are each divided into three outside nozzles 51, 52 and 53 by two or three partitioning walls 50 and smaller-diameter inside nozzles 5a, 5b and 5c are disposed centrally in the outside nozzles 51, 52 and 53 respectively. By simultaneously extruding different film-forming substances from the outside nozzles 51, 52 and 53 and filling substances from the inside nozzles 5a, 5b and 5c with the use of these composite nozzles 5, there can be produced seamless soft capsules 10 in which the filling substances c, d and h are encapsulated in the cells a, b and g formed from cell walls of different materials, as shown in Figures 7 and 9.

Figure 10 shows still another example of the composite nozzle 5 in which a large-diameter tube of an elliptical cross-sectional shape is divided into a large-diameter outside nozzle 51 and a small-diameter outside nozzle 52 by a partitioning wall 50 at a site about 1/3 as viewed from one end surface of the tube, inside nozzles 5a and 5b having a smaller diameter are disposed in the large-diameter outside nozzle 51 in spaced-apart relationship, and an inside nozzle 5c having a smaller diameter

is disposed centrally in the small-diameter outside nozzle 52.

When the composite nozzle 5 shown in Figure 10 is used, different film-forming substances and different filling substances are simultaneously extruded along the stream of the liquid medium in the apparatus shown in Figure 1 from the outside nozzles 51 and 52, and the inside nozzles 5a, 5b and 5c, respectively. Thus, a composite jet stream containing two independent streams of the filling substances c and h and a composite jet stream containing one stream of the filling substance b are formed simultaneously in the capsule-forming tank 6 as in Figure 1, and coalesced into a single composite jet stream. The single composite jet stream is successively cut in a predetermined size from its leading end in the flowing direction by the action of the pulsating flow of the liquid medium.

The soft capsule 10 produced in this way is a seamless soft capsule composed of a unitary structure of a cell a and two filling substances c and h independently encapsulated in it and a cell b and one filling substance d encapsulated in it, as shown in Figure II.

The soft capsule 10 shown in Figure II and the method of production using the composite nozzle shown in Figure 10 give a capsule in which two filling substances c and h are independently encapsulated in a cell having a cell wall of the same material. Hence, they are beneficial when different drugs which are to be released simultaneously from one cell a but should not be mixed beforehand are used as the filling substances c and h.

Even when the outside nozzles 51 and 52 of the composite nozzle 5 are not unitary but are slightly spaced from each other as shown in the embodiment given in Figure 12, composite jet streams extruded separately from the nozzles 51 and 52 are coalesced into a single composite jet stream by the pulsating flow of the liquid medium, and cut to a predetermined length from its leading end in the flowing direction. Hence, the method of this invention can be practiced in the same way by using the composite nozzle 5 shown in Figure 12.

The single composite jet stream formed along the flow of the liquid medium e may be cut to a predetermined length from its leading end in the flowing direction by intermittently increasing the speed of the downwardly flowing stream of the liquid medium e, and intermittently pulling off the composite jet stream downwardly by the quickened downwardly flowing liquid stream, instead of applying a pulsating flow of the liquid medium e sideways to the composite jet stream in the embodiments described above. By this alternative procedure, too, the single composite jet stream can be cut successively to a predetermined length.

According to this invention, one capsule con-

tains a plurality of cells whose cell walls are made of different materials. Hence, the present invention is suitable for filling both a substance to be released and absorbed in the stomach and a substance to be released and absorbed in the intestines, or at least two substances having different dissolving times, in a separated state in a single capsule. Since the soft capsule of the invention is seamless, the filled substances can be retained stably while preventing their deterioration by oxidation or otherwise. According to the method of this invention, capsules of any desired sizes can be produced, and capsules having a smaller size than in the prior art can be easily produced at low cost.

The following Example illustrates the present invention more specifically.

#### EXAMPLE I

Referring to Figure 1, a film-forming substance A was filled in tank 1, and a film-forming substance B, in tank 2. These film-forming substances A and B were extruded from composite nozzle 5 having a outside long diameter ( $d_L$ ) of 13 mm, an outside short diameter ( $d_s$ ) of 9 mm and a thickness of 1 mm (Figure 2) by metering pumps II and 2I. The amount of each of the film-forming substances A and B was 65.7 g/min.

In the meantime, a filling substance C was filled in tank 3, and another filling substance D, in tank 4. The filling substances C and D were extruded from nozzles 5a and 5b having an outside diameter ( $d_i$ ) of 3 mm, an inside diameter of 2 mm and a thickness of 0.5 mm (Figure 2) by metering pumps 3I and 4I. The amount of each of the filling substances extruded was 36 g/min. Composite jet streams composed of the film-forming substances A and B and the filling substances C and D flowed at a rate of 10 meters/min.

A paraffin oil as a cooling medium e within vessel 7 and heat-exchanger 72 was maintained at 3°C, and flowed downwardly in capsule-forming tank 6 at a flow rate of 15 m/min. A pulsating flow of the paraffin oil generated from pulse flow generator 74 was extruded at equal time intervals from pulse flow nozzle 8 accurately 15 times per second.

Within the capsule-forming tank, capsules were formed at a rate of 15 per second at intervals of about 11 mm. After drying, each of the capsules had a long diameter of 8 mm and a short diameter of 6 mm, and the amount of each of the filling substances was 40 mg per capsule.

The film-forming substance A is a solution consisting of 20 parts of gelatin, 5 parts by weight of glycerol, 8 parts by weight of sorbitol and 67 parts by weight of purified water which was maintained at about 60°C.

The film-forming substance B was a solution

consisting of 18 parts by weight of gelatin, 5 parts by weight of glycerol, 2.5 parts by weight of sodium alginate and 74.5 parts by weight of purified water which was maintained at about 60°C.

5 The filling substances C and D were solutions composed of different drugs which were maintained at about 25°C.

10 By the above procedure, there was produced a seamless soft capsule I0 which contained a core c composed of the filling substance C encapsulated in a gastric-soluble film a composed of the film-forming substance A and a core d composed of the filling substance D encapsulated in an enteric-soluble film b independently from each other, with the film portion separating the core c from the core d being of a double structure.

15 When the resulting soft capsule I0 was immersed in the first solution (gastric juice) stipulated in the Revised Method of Testing Disintegration in accordance with Japanese Pharmacopoeia, the film a dissolved in several minutes to release the core c, whereas the film b did not dissolve for more than 2 hours.

20 When the soft capsule I0 was immersed in the second solution (intestinal fluid) in the Revised Method of Testing Disintegration in accordance with Japanese Pharmacopoeia, both the films a and b dissolved within 2 to 3 minutes.

#### EXAMPLE 2

25 In the same way as in Example I, film-forming substances A and B were extruded from a composite nozzle having an outside long diameter ( $D_L$ ) of 7.5 mm, an outside short diameter ( $D_s$ ) of 3.5 mm and a thickness of 0.5 mm. The amount of each of the film-forming substances A and B extruded was 21.9 g/min.

30 In the meantime, filling substances C and D were extruded from nozzles 5a and 5b having an outside diameter ( $d_i$ ) of 1 mm and a thickness of 0.1 mm. The amount of each of the substances C and D extruded was 18.6 g/min. The speed of the composite jet stream at this time was 6 m/min. A paraffin oil was used as a cooling medium e and caused to flow in capsule-forming tank 6 at a rate of 22.5 m/min.

35 A pulsating flow of the paraffin oil generated from the pulse stream generator 74 was extruded from pulse stream nozzle 8 at equal time intervals accurately 50 times per second.

40 In capsule-forming tank 6, fifty capsules were formed per second at intervals of about 7.5 mm. After drying, each of the capsule had a long diameter of 3.5 mm and a short diameter of 2.5 mm. The amount of each of the filling substances C and D was about 6.2 mg.

**Claims**

1. A seamless soft capsule (10) containing encapsulated filling substances (c, d, h), at least one encapsulating wall being formed of a material (A, B) different from a material (A, B) forming another encapsulating wall, **characterized** in that said soft capsule (10) being composed of a plurality of cells (a, b, g) coalesced to each other, said filling substances (c, d, h) being encapsulated in the individual cells (a, b, g), the wall of at least one of said cells (a, b, g) being formed of a material (A, B) different from a material (A, B) forming the wall of at least one of the other cells (a, b, g). 5
2. The soft capsule (10) of claim 1, **characterized** in that at least one of the cells (a, b, g) and at least one of the other cells (a, b, g) are formed of cell wall materials (A, B) having different dissolving times in the digestive tract or different dissolving characteristics in the digestive tract. 10
3. The soft capsule (10) of claim 1, **characterized** in that the filling substance (C, D) encapsulated in the plurality of cells (a, b, g) are different from one another. 15
4. The soft capsule (10) of claim 1, **characterized** in that said capsule (10) being composed of two (a, b) or three (a, b, g) cells. 20
5. A method of producing the soft capsule (10) of claim 1, which comprises: 25
- (a) preparing a composite jet stream consisting of a stream of a film-forming liquid substance (A, B) for forming an encapsulating wall and within said stream of a film-forming substance (A, B) a single stream, or a plurality of independent streams, of a filling substance (C, D) having flowability, 30
- (b) advancing the composite jet stream into and through a stream of a liquid medium (e) substantially incapable of dissolving the film-forming liquid substance (A, B) in the flowing direction of the liquid medium stream (e), 35
- (c) obtaining soft capsules (10) from a predetermined length of the composite jet stream successively from its leading end in the liquid medium stream (e), and 40
- (d) solidifying the walls of the resulting soft capsules (10); 45
- characterized** in that 50
- (1) step (a) comprises preparing a plurality of composite jet streams each consisting of a stream of film-forming liquid substance (A, B) for forming a cell wall and within said stream of a film-forming liquid substance (A, B) a single stream, or a plurality of independent streams, of a filling substance (C, D) having flowability, the film-forming liquid substance (A, B) in at least one of the composite jet streams being different from the film-forming liquid substance (A, B) in at least one of the other composite jet streams, 55
- (2) step (b) comprises advancing the plurality of composite jet streams in closely spaced relationship into and through said stream of a liquid medium (e) substantially incapable of dissolving the film-forming liquid substance (A, B) in the flowing direction of the liquid medium stream (e),
- (3) an additional step is provided between steps (b) and (c), said additional step comprises coalescing the adjacent composite jet streams to each other to form a single composite jet stream in the liquid medium stream (e),
- (4) step (c) comprises cutting said single composite jet stream obtained from said coalescing, to a predetermined length successively from its leading end in the liquid medium stream (e), and
- (5) step (d) comprises solidifying the cell walls of the resulting soft capsule (10).
6. The method of claim 5, **characterized** in that each of said plurality of composite jet streams is formed by using a composite nozzle (5) comprised of an outside nozzle (51, 52, 53) and at least one small-diameter inside nozzle (5a, 5b, 5c) disposed therein and simultaneously extruding the film-forming liquid substance (A, B) from the outside nozzle and the filling substance (C, D) from the inside nozzle (5a, 5b, 5c). 60
7. The method of claim 5, **characterized** in that the cutting of the single composite jet stream is carried out by intermittently applying a pulsating flow of a liquid medium (e) from a pulse stream nozzle (8) surrounding the single composite jet stream. 65
8. The method of claim 5, **characterized** in that the film-forming liquid substance (A, B) in at least one of the plurality of composite jet streams has a different dissolving time in the digestive tract or a different dissolving characteristic in the digestive tract from the film-forming liquid substance (A, B) in at least one 70

of the other composite jet streams.

9. The method of claim 5, characterized in that the plurality of composite jet streams contain different filling substances. 5

### Revendications

1. Capsule molle sans soudure (10) contenant des substances de remplissage encapsulées (c, d, h), l'une au moins des parois encapsulantes étant formée d'une matière (A, B) différente d'une matière (A, B) formant une autre paroi encapsulante, caractérisée en ce que ladite capsule molle (10) est composée de plusieurs cellules (a, b, g) fusionnées entre elles, lesdites substances de remplissage (c, d, h) étant encapsulées dans les cellules individuelles (a, b, g), la paroi d'au moins l'une desdites cellules (a, b, g) est formée d'une matière (A, B) différente d'une matière (A, B) formant la paroi d'au moins l'une des autres cellules (a, b, g).

2. Capsule molle (10) selon la revendication 1, caractérisée en ce qu'au moins l'une des cellules (a, b, g) et au moins l'une des autres cellules (a, b, g) sont formées de matières de paroi cellulaire (A, B) ayant des temps de dissolution différents dans le tube digestif ou des caractéristiques de dissolution différentes dans le tube digestif. 25

3. Capsule molle (10) selon la revendication 1, caractérisée en ce que les substances de remplissage (C, D) encapsulées dans les diverses cellules (a, b, g) sont différentes entre elles. 35

4. Capsule molle (10) selon la revendication 1, caractérisée en ce que ladite capsule (10) est composée de deux (a, b) ou trois (a, b, g) cellules. 40

5. Procédé de production de la capsule molle (10) de la revendication 1, qui consiste à :

(a) préparer un courant de jet composé consistant en un courant d'une substance filmogène liquide (A, B) destinée à former une paroi encapsulante et, à l'intérieur dudit courant de substance filmogène (A, B), un courant unique ou plusieurs courants indépendants d'une substance de remplissage (C, D) capable de s'écouler,

(b) faire avancer le courant de jet composé dans et à travers un courant d'un milieu liquide (e) sensiblement incapable de dissoudre la substance filmogène liquide (A, B), dans le sens d'écoulement du courant

de milieu liquide (e),  
 (c) former des capsules molles (10) dans le courant de milieu liquide (e) à partir d'une longueur prédéterminée du courant de jet composé, successivement à partir de son extrémité avant, et  
 (d) solidifier les parois des capsules molles (10) résultantes ;

caractérisé en ce que

(1) l'étape (a) consiste à préparer plusieurs courants de jet composés consistant chacun en un courant de substance liquide filmogène (A, B) destinée à former une paroi cellulaire et, à l'intérieur dudit courant de substance liquide filmogène (A, B), un courant unique ou plusieurs courants indépendants d'une substance de remplissage (C, D) capable de s'écouler, la substance filmogène liquide (A, B) de l'un au moins des courants de jet composés étant différente de la substance filmogène liquide (A, B) de l'un au moins des autres courants de jet composés,

(2) l'étape (b) consiste à faire avancer lesdits courants de jet composés, en relation d'étroite proximité, dans et à travers ledit courant de milieu liquide (e) sensiblement incapable de dissoudre la substance filmogène liquide (A, a), dans le sens d'écoulement du courant de milieu liquide (e),  
 (3) une étape supplémentaire est prévue entre les étapes (b) et (c), ladite étape supplémentaire consistant à fusionner entre eux les courants de jet composés adjacents pour former un courant de jet composé unique dans le courant de milieu liquide (e),  
 (4) l'étape (c) consiste à sectionner à une longueur prédéterminée ledit courant de jet composé unique obtenu par ladite fusion,

successivement à partir de son extrémité avant dans le courant de milieu liquide (e), et  
 (5) l'étape (d) consiste à solidifier les parois cellulaires de la capsule molle (10) résultante.

45 6. Procédé selon la revendication 5, caractérisé en ce que chacun desdits courants de jet composés est formé en utilisant une tuyère composée (5) constituée d'une tuyère extérieure (51, 52, 53) et d'au moins une tuyère intérieure de petit diamètre (5a, 5b, 5c) disposée dans celle-ci et en extrudant simultanément la substance filmogène liquide (A, B) par la tuyère extérieure et la substance de remplissage (C, D) par la tuyère intérieure (5a, 5b, 5c). 50

55 7. Procédé selon la revendication 5, caractérisé en ce que le sectionnement du courant de jet

- composé unique est effectué en appliquant périodiquement un courant pulsatoire d'un milieu liquide (e) par une tuyère (8) de courant pulsatoire entourant le courant de jet composé unique.
8. Procédé selon la revendication 5, caractérisé en ce que la substance filmogène liquide (A, B) d'au moins l'un des plusieurs courants de jet composés présente un temps de dissolution différent dans le tube digestif ou une caractéristique de dissolution différente dans le tube digestif de ce que présente la substance filmogène liquide (A, B) d'au moins l'un des autres courants de jet composés.
9. Procédé selon la revendication 5, caractérisé en ce que les courants de jet composés contiennent des substances de remplissage différentes.
- Patentansprüche**
1. Nahtlose weiche Kapsel (10), die eingekapselte Füllsubstanzen (c, d, h) enthält, wobei wenigstens eine Einkapselungswand aus einem Material (A, B) ausgebildet ist, das von einem Material (A, B), welches eine andere Einkapselungswand bildet, unterschiedlich ist, dadurch **gekennzeichnet**, daß die weiche Kapsel (10) aus einer Mehrzahl von Zellen (a, b, g) zusammengesetzt ist, die miteinander zusammengeflossen sind, wobei die Füllsubstanzen (c, d, h) in den individuellen Zellen (a, b, g) eingekapselt sind, wobei die Wand von wenigstens einer der Zellen (a, b, g) aus einem Material (A, B) ausgebildet ist, das unterschiedlich von einem Material (A, B) ist, welches die Wand von wenigstens einer der anderen Zellen (a, b, g) bildet.
2. Weiche Kapsel (10) nach Anspruch 1, dadurch **gekennzeichnet**, daß wenigstens eine der Zellen (a, b, g) und wenigstens eine der anderen Zellen (a, b, g) aus Zellwandmaterialien (A, B) ausgebildet sind, welche unterschiedliche Auflösungszeiten in dem Verdauungssystem oder unterschiedliche Auflösungscharakteristika in dem Verdauungssystem haben.
3. Weiche Kapsel (10) nach Anspruch 1, dadurch **gekennzeichnet**, daß die Füllsubstanzen (C, D), die in der Mehrzahl von Zellen (a, b, g) eingekapselt sind, unterschiedlich voneinander sind.
4. Weiche Kapsel (10) nach Anspruch 1, dadurch **gekennzeichnet**, daß die Kapsel (10) aus zwei (a, b) oder drei (a, b, g) Zellen zusammengesetzt ist.
5. Verfahren zum Herstellen der weichen Kapsel (10) nach Anspruch 1, welches folgendes umfaßt:
- (a) Herstellen eines zusammengesetzten Strahlstroms, der aus einem Strom von einer filmbildenden flüssigen Substanz (A, B) zum Ausbilden einer Einkapselungswand und innerhalb dieses Stroms von einer filmbildenden Substanz (A, B) aus einem einzelnen Strom oder einer Mehrzahl von unabhängigen Strömen von einer Füllsubstanz (C, D), die Fließfähigkeit hat, besteht,
- (b) Vorwärtsbewegen des zusammengesetzten Strahlstroms in und durch einen Strom aus einem flüssigen Medium (e), das im wesentlichen unfähig ist, die filmbildende flüssige Substanz (A, B) aufzulösen, in der Fließrichtung des flüssigen Mediumstroms (e),
- (c) Erhalten von weichen Kapseln (10) von einer vorbestimmten Länge des zusammengesetzten Strahlstroms aufeinanderfolgend von dessen voreilendem Ende in dem flüssigen Mediumstrom (e), und
- (d) Verfestigen der Wände der resultierenden weichen Kapseln (10);
- dadurch **gekennzeichnet**, daß
- (1) der Schritt (a) das Herstellen einer Mehrzahl von zusammengesetzten Strahlströmen umfaßt, von denen jeder aus einem Strom von filmbildender flüssiger Substanz (A, B) zum Ausbilden einer Zellwand und innerhalb dieses Stroms von einer filmbildenden flüssigen Substanz (A, B) aus einem einzelnen Strom oder einer Mehrzahl von unabhängigen Strömen von einer Füllsubstanz (C, D), die Fließfähigkeit hat, besteht, wobei die filmbildende flüssige Substanz (A, B) in wenigstens einem der zusammengesetzten Strahlströme unterschiedlich von der filmbildenden flüssigen Substanz (A, B) in wenigstens einem der anderen zusammengesetzten Strahlströme ist,
- (2) der Schritt (b) das Vorwärtsbewegen der Mehrzahl von zusammengesetzten Strahlströmen in eng beabstandeter Beziehung in und durch den Strom aus einem flüssigen Medium (e), das im wesentlichen unfähig ist, die filmbildende flüssige Substanz (A, B) aufzulösen, in der Fließrichtung des flüssigen Mediumstroms (e) umfaßt,
- (3) ein zusätzlicher Schritt zwischen den Schritten (b) und (c) vorgesehen ist, wobei

- dieser zusätzliche Schritt das Zusammenfließen der benachbarten zusammengesetzten Strahlströme miteinander, so daß ein einziger zusammengesetzter Strahlstrom in dem flüssigen Mediumstrom (e) gebildet wird, umfaßt, 5
- (4) der Schritt (c) das Zerschneiden des einzigen zusammengesetzten Strahlstroms, der aus dem Zusammenfließen erhalten wird, zu einer vorbestimmten Länge aufeinanderfolgend von dessen voreilendem Ende in dem flüssigen Mediumstrom (e) umfaßt, und 10
- (5) der Schritt (d) das Verfestigen der Zellwände der resultierenden weichen Kapsel (10) umfaßt. 15
6. Verfahren nach Anspruch 5, dadurch **gekennzeichnet**, daß jeder aus der Mehrzahl der zusammengesetzten Strahlströme durch Verwendung einer zusammengesetzten Düse (5) gebildet wird, die aus einer äußeren Düse (51, 52, 53) und wenigstens einer inneren Düse (5a, 5b, 5c) von kleinem Durchmesser, die darin angeordnet ist, besteht, und daß die filmbildende flüssige Substanz (A, B) aus der äußeren Düse und die Füllsubstanz (C, D) aus der inneren Düse (5a, 5b, 5c) gleichzeitig extrudiert werden. 20
7. Verfahren nach Anspruch 5, dadurch **gekennzeichnet**, daß das Zerschneiden des einzigen zusammengesetzten Strahlstroms durch intermittierendes Anwenden einer pulsierenden Strömung eines flüssigen Mediums (e) von einer Impulstromdüse (8), welche den einzigen zusammengesetzten Strahlstrom umgibt, ausgeführt wird. 25
8. Verfahren nach Anspruch 5, dadurch **gekennzeichnet**, daß die filmbildende flüssige Substanz (A, B) in wenigstens einem aus der Mehrzahl der zusammengesetzten Strahlströme eine unterschiedliche Auflösungszeit in dem Verdauungssystem oder eine unterschiedliche Auflösungscharakteristik in dem Verdauungssystem gegenüber der filmbildenden flüssigen Substanz (A, B) in wenigstens einem der anderen zusammengesetzten Strahlströme hat. 30
9. Verfahren nach Anspruch 5, dadurch **gekennzeichnet**, daß die Mehrzahl von zusammengesetzten Strahlströmen unterschiedliche Füllsubstanzen enthält. 35
